#### Abstract

User password or PIN Number has become mandatory in every secret communication, financial and monitory transactions these days. Communicating and strong one-time password or PIN number increases the potential rise of the security. Crypto Council for Innovation (CCI) is developing many PIN security requirements as encrypted symmetric keys in structures called key blocks, which contain protected keys, usage constraints. In these key blocks, there is no expectation that previously established keys can be reused. In the present paper, password or PIN encryption and migration technique is explained using Catalan number sequences. Here the encrypted password or PIN is inserted in a long random text at different positions and the text is communicated to receiver. The positions of the inserted PIN characters are secret between the sender and the receiver.

Key words: Catalan Number $\mathrm{C}_{\mathrm{n}}$, Polygon triangulation $\mathrm{T}_{\mathrm{n}}$, Encryption, Decryption

## I. INTRODUCTION

Due to the COVID pandemic many financial transactions are being done online via confirmation of OTP sent to mobile phones which is expected to be well secured. As the password or PIN is very small in size, it can be broken easily in communication mechanism. Crypto currency is a digital or virtual form of currency which uses cryptography for securing the transactions. It is ever expanding, runs on block chain where one exchanges currency with a peer using digital wallet. For the transaction, we need password. Crypto currency units are creating through mining Process. Text based and numerical based password or PIN is a popular authentication mechanism, but it is troublesome in communication aspects. As password or PIN is very small, main problem arises from memorability and reusing issues resulting into vulnerability to dictionary attacks. Moreover, migration of the user Password or PIN from one source to the other is quite difficult in Client/Server systems. Encrypted password or PIN can be stored securely in the directory of server and can be migrated across the internet with protection. Also unauthorized access of user password or PIN from the server can be prevented. The present paper explains password or PIN encryption and migration technique from one source to the other based on Catalan number sequence and polygon triangulation technique. A double encrypted password or PIN is inserted at different positions of a random text, communicated across the public channel. Encrypted mechanism is
secret between legitimate users and servers. The positions where the encrypted password or PIN characters are inserted are the secret keys (Decimal numbers) between the users.

## Catalan Numbers:

Catalan numbers were discovered by a Belgian mathematician Eugene Catalan. It is a sequence of natural numbers denoted by $\mathrm{C}_{\mathrm{n}}$.

The formula for number sequence is

$$
\begin{equation*}
\mathrm{C}_{\mathrm{n}}=\frac{2 \mathrm{n}!}{(\mathrm{n}-1)!\mathrm{n}!}=\frac{1}{\mathrm{n}+1}\binom{2 \mathrm{n}}{\mathrm{n}} \mathrm{n} \geq 0 \tag{1}
\end{equation*}
$$

The following table 1 shows the Catalan numbers for $\mathrm{n} \in\{1,2, \ldots, 20\}$ calculated with formula 1.

Table 1: First 20 values of Catalan numbers

| n | $\mathrm{C}_{\mathrm{n}}$ | n | $\mathrm{C}_{\mathrm{n}}$ |
| :--- | :--- | :--- | :--- |
| 1 | 1 | 11 | 58,786 |
| 2 | 2 | 12 | 208,012 |
| 3 | 5 | 13 | 742,900 |
| 4 | 14 | 14 | $2,674,440$ |
| 5 | 42 | 15 | $9,694,845$ |
| 6 | 132 | 16 | $35,357,670$ |
| 7 | 429 | 17 | $129,644,790$ |
| 8 | 1,430 | 18 | $477,638,700$ |
| 9 | 4,862 | 19 | $1,767,263,190$ |
| 10 | 16,796 | 20 | $6,564,120,420$ |

For example,

$$
\text { If } \mathrm{n}=20, \mathrm{C}_{\mathrm{n}}=6564120420
$$

Catalan number using Euler`s triangulation problem can also be defined as

$$
\begin{equation*}
\mathrm{C}_{0}=1, \mathrm{C}_{1}=1 \quad \mathrm{C}_{\mathrm{n}}=\frac{4 \mathrm{n}-2}{\mathrm{n}+1} \mathrm{C}_{\mathrm{n}-1} \quad \mathrm{n} \geq 2 . \tag{2}
\end{equation*}
$$

## Ubiquitous Nature of Catalan Numbers:

Like Fibonacci and Lucas numbers Catalan numbers have ubiquitous nature. Catalan sequences have many applications in Combinatorics in finding the number of lattice paths of mountain ranges (Dyck paths), in formation of binary trees, in parenthesizing problem, in abstract algebra and sports. Polygon triangulation and Catalan numbers have several applications in cryptography $[2,3,8]$. They are used to design encryption algorithms, Cryptography key generation algorithms in the history of cryptography.

## Polygon Triangulation:

In computational geometry, dividing the polygon area into triangles with non-intersecting diagonals is called polygon triangulation. For a complex polygon, the triangulation is just drawing the diagonals between nonadjacent vertices.

It has many applications in curved geometry, in art gallery problem for obtaining 3D object Representations, Computer graphics and in CAD programs etc..Catalan number is a number sequence which is the solution of many combinatorial problems. Polygon Triangulation is a problem used in discovery of Catalan numbers. A Convex n-gon can be decomposed into ( n 2) triangles. To associate the Polygon triangulation and Catalan number, the number of triangles with n -angle is denoted by $\mathrm{T}_{\mathrm{n}}$.
$\mathrm{T}_{\mathrm{n}}=\mathrm{C}_{(\mathrm{n}-2), \mathrm{n}} \geq 3$ $\qquad$

$$
\begin{equation*}
\mathrm{T}_{\mathrm{n}}=\frac{1}{n-1}\binom{2 \mathrm{n}-4}{\mathrm{n}-2}=\frac{(2 n-4)!}{(n-1)!(n-2)!} . \tag{3}
\end{equation*}
$$

For polygon triangulation, first the polygon is decomposed into trapezoids; the Trapezoids are divided into monotone polygons, then the monotone polygons into Triangles. This algorithm is called Seidel's Algorithm. A Polygon with 10 vertices requires 0.9 milli seconds, 50 vertices require 3.5 milli seconds, 100 vertices 6.7 milli seconds of time. So, a polygon with 1 kb vertices requires 97.6 milli seconds.

## II. LITERATURE SURVEY

M. Yildirm, I.Mackie[1] proposed Password security and memorability technique for encouraging the users. In that chapter they divided the entire group of users into two parts
and applied empherical formula. Shay et-al[2] specified that the users are not aware of construction of strong passwords. Florencio, D. et-al[3] studied the average password required accounts for a user in a day. Perrig [4] proposed suitable protocol for security levels as key agreement protocols using binary tree. Mishra, Swetha[5] designed an analysis of password-based authentication in her doctoral thesis. In that thesis she developed password hashing algorithm and analysed exiting password mechanisms. Katha chanda [6] studied security analysis and strength of passwords. In that chapter the author carried out different tests to evaluate the resistance of the password against brute force attacks. D. Sravana Kumar et.al [7] designed password encryption scheme based on elliptic curve cryptography over finite fields. Saracevic et-al [8] proposed Possibilities of applying the triangulation method in the biometric identification process. Amounas et-al [9] designed Novel Encryption Schemes Based on Catalan Numbers. Higgins P.M.[10] explained how different kinds of numbers arose and why they are useful. Horak Pet-al [11] proposed an application of Combinatorics in Cryptography. In that article, they focused on the MaxMinMax problem and present results over finite and infinite fields. Koscielny C et-al [12] proposed Theoretical Foundations and Practical Applications. In that chapter, the author introduced some basic mathematical concepts necessary to understand the design of modern cryptographic algorithms and protocols.

## III. PROPOSED SCHEME

The present password or PIN encryption and migration technique is well suited for transmitting one time password (OTP) in Client/Server applications. The mechanism works on Catalan number sequence and Polygon triangulation algorithms.

If two legitimate users want to communicate password or PIN or secret key (small in size) for future communications, before transmission they agree upon to use a natural number ' $n$ ' which is a secret key for encrypting and migrating encrypted password or PIN, particularly a big composite number having more than a non-trivial factors. Example: 36 have 6 non-trivial factors 2,3,4,6,9,12.

In those factors first four numbers in increasing order are to be considered say $\mathrm{n}_{1}, \mathrm{n}_{2}, \mathrm{n}_{3}, \mathrm{n}_{4}$. The sender also selects a random text with length greater than or equal to the biggest factor [decimal number] of the agreed upon composite number.

## ENCRYPTION:

1. For the four decimal numbers (factors) of the consented composite number corresponding Catalan number $\mathrm{C}_{\mathrm{n}}$ and polygon triangulation $\mathrm{T}_{\mathrm{n}}$ are calculated using the above mentioned formulae (1),(4).
2. The password or PIN is generally small in size consisting of a numerals say $\mathrm{M}_{1}, \mathrm{M}_{2}, \mathrm{M}_{3}, \mathrm{M}_{4}$. These four numerals are coded to ASCII equivalent binary values.
3. Let the Catalan number sequences for $\mathrm{n}_{1}, \mathrm{n}_{2}, \mathrm{n}_{3}$, $\mathrm{n}_{4}$ be $\mathrm{Cn}_{1}, \mathrm{Cn}_{2}, \mathrm{Cn}_{3}, \mathrm{Cn}_{4}$. These Catalan number sequences $\mathrm{Cn}_{1}, \mathrm{Cn}_{2}, \mathrm{Cn}_{3}, \mathrm{Cn}_{4}$ are adjusted to mod 256, corresponding ASCII binary equivalents are written.
4. The polygon triangulation number $\mathrm{Tn}_{1}, \mathrm{Tn}_{2}, \mathrm{Tn}_{3}, \mathrm{Tn}_{4}$ of the numbers $\mathrm{n}_{1}, \mathrm{n}_{2}, \mathrm{n}_{3}, \mathrm{n}_{4}$ are adjusted to mod 7 .

$$
\mathrm{Cn}_{\mathrm{i}}(\bmod 256)=\mathrm{ACn}_{\mathrm{i}}(\text { Adjusted } \mathrm{Cn}), \text { for } \mathrm{i}=1,2,3,4
$$

$\mathrm{Tn}_{\mathrm{i}}(\bmod 8)=\mathrm{ATn}_{\mathrm{i}}($ Adjusted Tn$)$, for $\mathrm{i}=1,2,3,4$
5. The ASCII binary of the first numeral $\mathrm{M}_{1}$ in the password or PIN is right rotated byATn ${ }_{1}$ times.

For instance $\mathrm{M}_{1}=11011011$ and $\mathrm{ATn}_{1}=4$ then $\mathrm{M}_{1}$ is right rotated four times.
Table 2: Right rotation operation by 4 times

| 1 | 1 | 0 | 1 | 1 | 0 | 1 | 1 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 1 | 1 | 1 | 0 | 1 | 1 | 0 | 1 |
| 1 | 1 | 1 | 1 | 0 | 1 | 1 | 0 |
| 0 | 1 | 1 | 1 | 1 | 0 | 1 | 1 |
| 1 | 0 | 1 | 1 | 1 | 1 | 0 | 1 | | $\left[\mathrm{M}_{1}, \mathrm{RR}(\mathrm{k})\right]$ |
| :--- | :--- |

6. Logical XOR operation is applied between the resulting binary numbers of step 5and ASCII 8-bit binary equivalent $\mathrm{ACn}_{1}$.

If $\mathrm{ACn}_{1}=55$ then ASCII binary of $\mathrm{ACn}_{1}=55$ is 00110111 and $\mathrm{M}_{1} \mathrm{R}=10111101$ (obtained from step 5)

Logical XOR is applied between $\mathrm{M}_{1} \mathrm{R}$ and $\mathrm{ACn}_{1 .(10111101)}$ and (00110111)
$\mathrm{M}_{1} \mathrm{R} \oplus \mathrm{ACn}_{1}:$
$\mathrm{M}_{1} \mathrm{R}: 10111101$
$\oplus$
$\mathrm{ACn}_{1}: 00110111$

$$
\mathrm{M}_{1} \mathrm{R} \oplus \mathrm{ACn}_{1}=10001010=\mathrm{M}_{1} \mathrm{C}
$$

$\mathrm{M}_{\mathrm{i}} \mathrm{R} \oplus \mathrm{ACn}_{\mathrm{i}}=\mathrm{M}_{\mathrm{i}} \mathrm{C}$, for $\mathrm{i}=1,2,3,4$
The ASCII symbol for this binary number is considered as first encrypted character $\mathrm{M}_{1} \mathrm{C}$.
7. Similar encryption procedure of steps 5,6 are applied on the other numerals of the password or PIN $M_{2}, M_{3}$ and $M_{4}$ to get the encrypted password or PIN $M_{2} C, M_{3} C$ and $M_{4} C$.
8. The sender of the message selects randomly large text having all types of characters as text, numerals, and special characters with a minimum size equal to greatest factor for the considered key (composite number). These encrypted characters inserted at the positions $\mathrm{n}_{1}$, $n_{2}, n_{3}$ and $n_{4}$ of the selected random text and communicated to the receiver as cipher text. The
 positions where the encrypted password or PIN characters are inserted may be communicated by the sender in a separate communication. For security concerns the composite number ' $n$ ' may be changed from time to time.

Minimum Size of the Random text $\geq \operatorname{Max}\left(\mathrm{n}_{1}, \mathrm{n}_{2}, \mathrm{n}_{3}, \mathrm{n}_{4}\right)$.
Decryption: Since it is a symmetric cipher the reverse process of encryption is decryption. The receiver after getting the large random text first picks up the encrypted password or PIN characters from their positions (known to both the legitimate entities). Reverse Logical XOR operation is applied on each character as in step 6

$$
\mathrm{M}_{\mathrm{i}} \mathrm{C} \oplus \mathrm{ACn}_{\mathrm{i}}=\mathrm{M}_{\mathrm{i}} \mathrm{R}, \text { for } \mathrm{i}=1,2,3,4
$$

Then the resulting binary stream is left rotated $k$ times to get operation is applied on the resulting binary stream to get the M1. Corresponding ASCII character is the original password character.
[ $\left.\mathrm{M}_{1} \mathrm{R}, \mathrm{LR}(\mathrm{k})\right] \quad \mathrm{M}_{1}$

## IV. EFFECTIVE UTILITY OF THE ALGORITHM IN CLIENT/SERVER SYSTEM

The present password encryption and insertion technique is well suited in client / server systems for transmitting one time password (OTP) to the client's transactions; also for drawing cash from ATM machines. Composite numbers having minimum four factors are stored in the central server. As the central server is powerful and provides the information to workstations, enormous number of composite numbers having at least four factors can be stored in it.

At the initial stage the client has to install the server application and has to register for the activation of client's application server. At that time of activation, central server stores the clients credentials and allots the client random composite numbers to choose one number among them with at least four non trivial factors for future transactions with the bank. When the client wants to make a transaction with the bank, requests the central server for OTP from his/her application server. Central server verifies the client's credentials, generates OTP (four digits), encrypts by using the allotted composite number to the client at the time of registration. The encrypted OTP is inserted in a random text at the positions of $n_{1,} n_{2}, n_{3}$ andn $n_{4}$ respectively. Client's application server recognizes the position of encrypted OTP character
(numerals), decrypts it and gives the OTP for the transaction. The decryption process is done at the server application.

Table. 3 CLIENT/SERVER SYSTEM

## Example

Consider Composite numbers $\mathbf{n}_{\mathbf{1}}=\mathbf{3}, \mathbf{n}_{\mathbf{2}}=\mathbf{9}, \mathbf{n}_{\mathbf{3}}=\mathbf{1 6}, \mathbf{n}_{4}=\mathbf{2 2}$
Take Password $\left(\mathbf{M}_{1} \mathbf{M}_{2} \mathbf{M}_{3} \mathbf{M}_{4}\right)=(\mathbf{1} \mathbf{4} \mathbf{2} \mathbf{6})$
Consider the random Text: GITAM INSTITUTE OF SCIENCES

## V. Security Analysis and Conclusions

In password or PIN communication mechanisms, main security issues arise since the password or PIN is very small merely number or text characters or special characters. Due to the small size no big deal, it can be cracked very easily and can be tampered. To avoid tracking and stealing of PIN by shoulder surfing when a customer withdraws money from ATM machines, to stop misuse and unnecessary involvement of third party in transactions an indirect PIN entry method safe and more secure. Covert form of password or PIN provides integrity and confidentiality of the sending information. In the present designed password or PIN the password is double encrypted and inserted at different positions of random text and transmitted through insecure channel. The encryption technique and the location of encrypted characters are understanding between the parties. Only one secret key a composite number ' $n$ ' is sharing which can be varied time to time to avoid key compromise. The original password or PIN characters are encrypted using Catalan number sequence and polygon triangulation sequence. Since the adversary is unaware of the password or PIN positions man-in-middle attack is highly impossible here to implement. In any case the positions are compromised, the characters are disguised. So, the algorithm developed here is free from all the security issues.
