#### Abstract

Research with the title: An Upper Bound on The Partition Dimension of Comb Product Graph Wheel and Path. This research is the development of the results of calculations, research methods with a qualitative model approach to the partition dimensions of the comb product between the wheel and path graph investigated in this study. The main objective in this research is to determine the partition dimension of the upper bound of this graph. To achieve optimal results, the researcher expands the wheel graph completion partition to find the comb product graph completion partition. The results of this study provide an upper bound on the partition dimensions of the comb product graph between the wheel graph and the path as the main result, throughout this section, the graphs $W_{n}$ for $n \geq 3$ is the wheel graph with $n+1$ vertices. The path graphs $P_{m}$ for $m \geq 1$ is a graph with $V\left(P_{m}\right)=$ $\left\{\mathrm{v}_{1}, \mathrm{v}_{2}, \ldots, \mathrm{v}_{-} \mathrm{m}\right\}$ and $E\left(\mathrm{P}_{\mathrm{m}}\right)=\left\{\mathrm{v}_{1}, \mathrm{v}_{2}, \mathrm{v}_{2}, \mathrm{v}_{3}, \ldots, \mathrm{v}_{\mathrm{m}-1}, \mathrm{v}_{\mathrm{m}}\right\}$.

 The lower limit of the partition dimensions should be examined further in future research.Keywords: Partition dimensions, comb product graph, wheel and path.

## 1. Introduction

Assume G is a connected graph. Let $\mathrm{v}, \mathrm{w} \in \mathrm{V}(\mathrm{G})$, the distance $\mathrm{d}(\mathrm{v}, \mathrm{w})$ is the length of a shortest path between them. It is well known that the concept of distance between two vertices in a connected graph can be used to describe the vertices in two ways. First, every vertex in V(G) can be represented by the metric with respect to a subset of $V(G)$. The second representation is the metric with respect to a partition of $V(G)$. For an ordered subset $W=\left\{w_{1}, w_{2}, \ldots, w_{k}\right\}$ of $\mathrm{V}(\mathrm{G})$ and a vertex w of $G$ the metric representation of v with respect to W is $\mathrm{r}(\mathrm{w} \mid \mathrm{W})=$ $\left(d_{1}, d_{2}, \ldots, d_{k}\right)$, where $d_{i}=d\left(w, w_{i}\right)$. Slater (Slater, 1975) and Harrary and Melter (F. Harary, 1976) independently introduced this representation. Finding the metric dimension and a
resolving set of connected graphs is the key difficulty in this area. If every vertex in G have distinct representations with regard to $\mathrm{W}, \mathrm{W}$ is called a resolving set for G . A basis for G is a resolving set with the minimum cardinality. The metric dimension of G is the number of elements in a basis for G , which is denoted by $\beta(\mathrm{G})$. The $\beta(\mathrm{G})$ is studied in (G. Chartrand L. E., 2000), (G. Chartrand C. P., 2000), (J. Caceres C. H., 2005), (J. Caceres C. H., 2007), (Tomescu, 2008). In chemistry, the idea of metric dimension is used to represent chemical compounds (S. Khuller, 1996) and has certain applications in robot navigation (S. Khuller, 1996). (G. Chartrand L. E., 2000). This principle can also be seen in coin weighing problems (A. Sebo, 2004) and Mastermind game techniques (Goddard, Static Mastermind, 2003). (Goddard, Mastermind revisited, 2004).

A variation representation of the previous one is the metric vector of a vertex with respect to a partition of $\mathrm{V}(\mathrm{G})$. We define the distance $\mathrm{d}(\mathrm{v}, \mathrm{S})$ between v and S by $\mathrm{d}(\mathrm{v}, \mathrm{S})=$ $\min \{d(v, w) \mid w \in S\}$ for every vertex $v \in V(G)$ and every subset $S$ of $V(G)$. Given an ordered partition $\Omega=\left\{\mathrm{S}_{1}, \mathrm{~S}_{2}, \ldots, \mathrm{~S}_{\mathrm{k}}\right\}$ of $\mathrm{V}(\mathrm{G})$, the partition representation of a vertex v with respect to the partition $\Omega$ is $\mathrm{r}(\mathrm{v} \mid \Omega)=\left(\mathrm{d}\left(\mathrm{v}, \mathrm{S}_{1}\right), \mathrm{d}\left(\mathrm{v}, \mathrm{S}_{2}\right), \ldots, \mathrm{d}\left(\mathrm{v}, \mathrm{S}_{\mathrm{k}}\right)\right)$. If any pair of different vertices $u, v \in V(G)$ has a distinct vector representation with regard to the partition $\Omega$, that is $r(u \mid \Omega) \neq$ $\mathrm{r}(\mathrm{v} \mid \Omega)$, we call $\Omega$ a resolving partition of G . For a graph G , the partition dimension $\mathrm{pd}(\mathrm{G})$, is the least number of sets in any resolving partition. Chartrand et.al introduced partition dimension and resolving partition of a connected graph (G. Chartrand E. S., 2000). (M. Fehr, 2006), and (Tomescu, 2008) also investigates pd(G). It is natural to think that $\beta(\mathrm{G})$ and $\mathrm{pd}(\mathrm{G})$ are linked. It is proved in (G. Chartrand E. S., 2000) that for all connected graph G that isn't trivial, we have $\operatorname{pd}(\mathrm{G}) \leq \beta(\mathrm{G})+1$.

The $\mathrm{pd}(\mathrm{G})$ for some specific classes of graphs have been known up to now. The values of the partition dimension is usually the results achieved but some other graph only get the bound of the partition dimension. Rodríguez et.al (Juan A. Rodríguez-Velázquez, 2014) put an upper bound of $\mathrm{pd}(\mathrm{T})$ where T is a tree. For circulant graphs, its partition dimension investigated by Grigorius et.al (Cyriac Grigorious, 2014). Tomescu et.al (I. Tomescu, 2007) provide a bound for $\mathrm{pd}\left(\mathrm{W}_{\mathrm{n}}\right)$ with $\mathrm{n} \geq 4$.

Theorem 1. Let $\mathrm{n}>3$ be an integer. If p is the lowest prime number with $\mathrm{p}(\mathrm{p}-1) \geq \mathrm{n}$, then $\left[(2 n)^{1 / 3}\right\rceil \leq \mathrm{pd}\left(\mathrm{W}_{\mathrm{n}}\right) \leq \mathrm{p}+1$. In graph theory, there are known operations of one graph such as subgraphs, subdivision. Also, there are operations between two or more graphs, for example the corona product, Cartesian product, union, normal, addition, and comb product. Many authors have looked into the graph's partition dimension from graph operations, including as corona product graphs (E. T. Baskoro, 2012), Cartesian product graphs (I. G. Yero J. A.-V., 2010), strong product graphs (I. G. Yero M. J., 2014), subdivision of complete graphs (Amrullah, 2015). In addition, Haryeni et.al (D. O. Haryeni, 2017) have studied the partition dimensions of disconnected graphs. Especially for the comb product graphs, Suhadi et al. conducted research on the graph's metric dimension (Suhadi W. S., 2017). While the partition dimensions of the comb product graphs in some cases have been studied in (Alfarisi, 2017), (Faisal, 2019).

Comb product graphs were originally introduced by Hora and Obata (Akihito Hora, 2007). These graphs are interesting to study because the structure is similar to chemical molecules, so it can be used to model specific chemical molecules. Consider two connected graphs, G and $\Gamma$.

Assume that $o$ is a vertex in $\Gamma$. The comb product between $G$ and $\Gamma$, denoted by $G \triangleright \Gamma$, is the graph with $V(G \triangleright \Gamma)=\{(x, y) \mid x \in V(G), y \in V(\Gamma)\} \quad$ and $\quad(x, y)(w, z) \in E(G \triangleright \Gamma)$ whenever $x=w$ and $y z \in E(\Gamma)$, or $x w \in E(G)$ and $y=z=o$. In this work, we give an upper bound for $\mathrm{pd}\left(\mathrm{W}_{\mathrm{n}} \triangleright_{\mathrm{o}} \mathrm{P}_{\mathrm{m}}\right)$ where $\mathrm{W}_{\mathrm{n}} \triangleright_{\mathrm{o}} \mathrm{P}_{\mathrm{m}}$ is the comb product of the wheel and path graph. For $\mathrm{n} \geq 3$, wheel graph $\mathrm{W}_{\mathrm{n}}$ is a graph built by linking the single vertex in graph $\mathrm{K}_{1}$ to all vertices of the cycle $C_{n}$ with $V\left(C_{n}\right)=\left\{c_{0}, c_{1}, \ldots, c_{n-1}\right\}$. As a result, $W_{n}$ has $n+1$ vertices. The center is the single vertex of $K_{1}$ in the $W_{n}$, while the rim is the vertices of $V\left(C_{n}\right)$. We consider the partition dimension of $W_{n} \triangleright_{o} P_{m}$ where $P_{m}$ is a path with $m$ vertices and $o$ is a vertex of $\mathrm{P}_{\mathrm{m}}$ with degree 1 .

## 2. Method

This type of research is qualitative research. This research aims to check the partition dimensions for a special graph class, namely the graph of the comb product between two connected graphs. In this study, we take a comb product between wheel graphs and a path. We gain an upper bound on the $\operatorname{pd}\left(W_{n} \triangleright_{o} P_{m}\right)$ this scenario. The first step in this investigation is to review the literature on the $\mathrm{pd}\left(\mathrm{W}_{\mathrm{n}}\right)$. Then we construct a resolving partition of $\mathrm{W}_{\mathrm{n}} \triangleright_{\mathrm{o}} \mathrm{P}_{\mathrm{m}}$ using resolving partition of $W_{n}$ to obtain the upper bound of $\mathrm{pd}\left(W_{n} \triangleright_{o} P_{m}\right)$.

## 3. Result and Discussion

Throughout this section, the graphs $W_{n}$ for $n \geq 3$ is the wheel graph with $n+1$ vertices. The path graphs $P_{m}$ for $m \geq 1$ is a graph with $V\left(P_{m}\right)=\left\{v_{1}, v_{2}, \ldots, v_{m}\right\}$, and $E\left(P_{m}\right)=$ $\left\{\mathrm{v}_{1} \mathrm{v}_{2}, \mathrm{v}_{2} \mathrm{v}_{3}, \ldots, \mathrm{v}_{\mathrm{m}-1} \mathrm{v}_{\mathrm{m}}\right\}$. We denote by $\mathbf{1}_{\mathrm{i}}$ the vector whose coordinates are all 1 , except one that equals 0 in the i-th coordinate. In general, we denote $\mathbf{k}_{\mathrm{i}}$ vector whose coordinates are all k , except one that equals 0 in the i -th coordinate.

Lemma 1. If $\Omega=\left\{S_{1}, S_{2}, \ldots, S_{k}\right\}$ is a resolving partition for $W_{n}$ with $\mathrm{c} \in \mathrm{S}_{\mathrm{t}}$ then $\mathrm{r}(\mathrm{c} \mid \Omega)=$ $\mathbf{1}_{\mathrm{t}} \in \mathbb{Z}^{\mathrm{k}}$.

Proof. It is clear that $d\left(c, S_{t}\right)=0$. Since $d(c, v)=1$ for every $v \in V\left(W_{n}\right)$ with $v \neq c$, hence $\mathrm{d}\left(\mathrm{v}, \mathrm{S}_{\mathrm{i}}\right)=1$ for every $\mathrm{i} \neq \mathrm{t}$.

Lemma 2. Let $\Omega=\left\{\mathrm{S}_{1}, \mathrm{~S}_{2}, \ldots, \mathrm{~S}_{\mathrm{k}}\right\}$ be a minimal resolving partition for $\mathrm{W}_{\mathrm{n}}$ and let $\mathrm{c}, \mathrm{c}_{\mathrm{j}} \in \mathrm{S}_{\ell}$. There exist $S_{u}$ with $u \neq \ell$ such that $d\left(c_{j}, S_{u}\right)=1$ if and only if $c_{j-1} \notin S_{\ell}$ or $c_{j+1} \notin S_{\ell}$ for every $j \in \mathbb{Z}_{\mathrm{n}}$.

Proof. Since $d\left(c_{j}, c_{j-1}\right)=d\left(c_{j}, c_{j+1}\right)=1$, there exists $S_{u} \in \Omega$ with $u \neq \ell$ such that $d\left(c_{j}, S_{u}\right)=1$ if and only if $c_{j-1} \in S_{u}$ or $c_{j+1} \in S_{u}$.

Corollary 1. Let $\Omega=\left\{\mathrm{S}_{1}, \mathrm{~S}_{2}, \ldots, \mathrm{~S}_{\mathrm{k}}\right\}$ be a minimal resolving partition for $\mathrm{W}_{\mathrm{n}}$ such that $\mathrm{c}_{\mathrm{i}} \in$ $S_{t}$ and either $c_{i-1} \notin S_{t}$ or $c_{i+1} \notin S_{t}$ for every $i \in \mathbb{Z}_{\mathrm{n}}$. Then there is no $\mathrm{v} \in \mathrm{V}\left(\mathrm{W}_{\mathrm{n}}\right)$ such that $\mathrm{r}(\mathrm{v} \mid \Omega) 2\left(\mathbf{1}_{\mathbf{j}}\right) \in \mathbb{Z}^{\mathrm{k}}$ for every. Type equation here.

Proof. If $v=c$ then $(v \mid \Omega) \neq 2\left(\mathbf{1}_{\mathbf{j}}\right)$. Let $\mathrm{v}=\mathrm{c}_{\mathrm{i}} \in \mathrm{S}_{\mathrm{t}}$ for $\mathrm{i} \in \mathbb{Z}_{\mathrm{n}}$ and suppose, without sacrificing generality, that $c \in S_{1}$. If $v$ is not in $S_{1}$, then $d\left(v, S_{1}\right)=d(v, c)=1$. Hence, $\mathrm{r}(\mathrm{v} \mid \Omega) \neq 2\left(\mathbf{1}_{\mathbf{j}}\right)$. If $\mathrm{v} \in \mathrm{S}_{1}$ then $\mathrm{d}\left(\mathrm{v}, \mathrm{S}_{1}\right)=0$. By Lemma 2 , there is a number u different with $t$ such that $d\left(v, S_{u}\right)=1$. Therefore, $r(v \mid \Omega) \neq 2\left(\mathbf{1}_{\mathbf{j}}\right)$.

Lemma 3. Let $\Omega=\left\{\mathrm{S}_{1}, \mathrm{~S}_{2}, \ldots, \mathrm{~S}_{\mathrm{k}}\right\}$ be a resolving partition for $\mathrm{W}_{\mathrm{n}}$ and define $\mathrm{S}_{\mathrm{i}}^{\prime}=$ $\left\{\left(\mathrm{v}, \mathrm{v}_{\mathrm{j}}\right) \mid \mathrm{v} \in \mathrm{S}_{\mathrm{i}}, 1 \leq \mathrm{j} \leq \mathrm{m}\right\}$ for every i. If $\Omega^{\prime}=\left\{\mathrm{S}_{1}^{\prime}, \mathrm{S}_{2}^{\prime}, \ldots, \mathrm{S}_{\mathrm{k}}^{\prime}\right\}$ then $\mathrm{r}\left(\left(\mathrm{v}, \mathrm{v}_{1}\right) \mid \Omega^{\prime}\right)=\mathrm{r}(\mathrm{v} \mid \Omega)$ for every $v \in V\left(W_{n}\right)$.

Proof. Pick a fix vertex $v \in S_{t}$, we know that $0 \leq d\left(v, S_{i}\right) \leq 2$ for every i. Consider any vertex $w$ in $W_{n}$ with $w \notin S_{t}$. It follows that $d\left(\left(v, v_{1}\right),\left(w, v_{j}\right)\right) \geq 2$ for $j \geq 2$. Consequently, $d\left(\left(v, v_{1}\right), S_{t}^{\prime}\right)=0$ and for $i \neq \operatorname{td}\left(\left(v_{1}, v\right), S_{i}^{\prime}\right)=d\left(\left(v_{1}, v\right),\left(w, v_{1}\right)\right)$ for some $w \in S_{i}$. Therefore, $d\left(\left(v_{1}, v\right), S_{i}^{\prime}\right)=d\left(\left(v, v_{1}\right),\left(v_{1}, w\right)\right)=d(v, w)=d\left(v, S_{i}\right)$.

Lemma 4. Let $\Omega$ be a minimal resolving partition that satisfy the necessary condition in Corollary 1. If $W_{n} \triangleright_{o} P_{m}$ is a comb product graph where $o$ is a vertex of $P_{m}$ with degree 1 , then $\operatorname{pd}\left(W_{n} \triangleright_{o} P_{m}\right) \leq \operatorname{pd}\left(W_{n}\right)$.

Proof. Let $\Omega=\left\{S_{1}, S_{2}, \ldots, S_{k}\right\}$ is a minimal resolving partition for $W_{n}$. Let $c$ be the central vertex and $c_{0}, c_{1}, \ldots, c_{n-1}$ be the rim vertices of $W_{n}$. Let $v_{1}, v_{2}, \ldots, v_{m}$ be the vertices of $P_{m}$ and $E\left(P_{m}\right)=\left\{v_{1}, v_{2}, \ldots, v_{m}\right\}$. We assume that $V\left(W_{n} \triangleright_{o} P_{m}\right)=\left\{\left(c_{k}, v_{1}\right) \mid k \in[1, n]\right\}$, and $\mathrm{l} \in$ $[1, \mathrm{~m}]\} \cup\left\{\left(\mathrm{c}, \mathrm{v}_{\mathrm{k}}\right) \mid, \mathrm{k} \in\{1, \ldots, \mathrm{~m}]\right\}$. The resolving partition $\Omega$ will induces a resolving partition of $W_{n} \triangleright_{o} P_{m}$. We define a subset of $V\left(W_{n} \triangleright_{o} P_{m}\right)$ as follows: $S_{i}^{\prime}=\left\{\left(v, v_{j}\right) \mid v \in S_{i}, j \in[1, m]\right\}$ for all i. Therefore, $\Omega^{\prime}=\left\{S_{1}^{\prime}, S_{2}^{\prime}, \ldots, S_{k}^{\prime}\right\}$ is a partition of $\mathrm{V}\left(\mathrm{W}_{\mathrm{n}} \triangleright_{\mathrm{o}} \mathrm{P}_{\mathrm{m}}\right)$. Consider $\Omega^{\prime}$ as an ordered partition, we claim that $\Omega^{\prime}$ is a resolving partition. Assume, without losing generality, that $\mathrm{c} \in \mathrm{S}_{1}$. We have that $\mathrm{r}\left(\left(\mathrm{c}, \mathrm{v}_{\mathrm{j}}\right) \mid \Omega^{\prime}\right)=\mathrm{j}\left(\mathbf{1}_{\mathbf{1}}\right)$ for $1 \leq \mathrm{j} \leq \mathrm{m}$. Let $\mathbf{x}, \mathbf{y} \in \mathrm{S}_{\mathrm{t}}^{\prime}$ for some t . Let $\mathbf{x}$ and $\mathbf{y}$ be two vertices of $W_{n} \triangleright_{o} P_{m}$ with $\mathbf{x}, \mathbf{y} \in S_{t}^{\prime}$. Case $1 . \mathbf{x}=\left(c, v_{j}\right), \mathbf{y}=\left(c_{i}, v_{\ell}\right)$ with $c_{i} \in S_{1}$

We have that $\mathrm{r}\left(\mathbf{y} \mid \Omega^{\prime}\right)=\mathrm{r}\left(\mathrm{c}_{\mathrm{i}} \mid \Omega\right)+(\ell-1)\left(\mathbf{1}_{\mathbf{1}}\right)$ for $1 \leq \ell \leq \mathrm{m}$. By Lemma 2 , there exists some coordinates in $r\left(c_{i} \mid \Omega\right)$ whose value are equal to 1 . Since $\Omega$ is a resolving partition, there exist some coordinates of $r\left(c_{i} \mid \Omega\right)$ whose value are equal to 2 . Hence, $r\left(c_{i} \mid \Omega\right) \neq s\left(\mathbf{1}_{\mathbf{1}}\right)$ for all integer $s$. We conclude, $r\left(\mathbf{x} \mid \Omega^{\prime}\right)$ is not the same as $r\left(\mathbf{y} \mid \Omega^{\prime}\right)$.

Case 2. $\mathbf{x}=\left(\mathrm{c}_{\mathrm{i}}, \mathrm{v}_{\mathrm{j}}\right), \mathbf{y}=\left(\mathrm{c}_{\mathrm{i}}, \mathrm{v}_{\ell}\right)$ with $\mathrm{j} \neq \ell$.
Since $r\left(\mathbf{x} \mid \Omega^{\prime}\right)=r\left(c_{i} \mid \Omega\right)+(j-1)\left(\mathbf{1}_{t}\right)$ and $r\left(\mathbf{x} \mid \Omega^{\prime}\right)=r\left(c_{i} \mid \Omega\right)+(\ell-1)\left(\mathbf{1}_{\mathrm{t}}\right)$, we can deduce that $\mathrm{r}\left(\mathbf{x} \mid \Omega^{\prime}\right) \neq \mathrm{r}\left(\mathbf{y} \mid \Omega^{\prime}\right)$.

Case 3. $\mathbf{x}=\left(\mathrm{c}_{\mathrm{i}}, \mathrm{v}_{\mathrm{j}}\right), \mathbf{y}=\left(\mathrm{c}_{\mathrm{q}}, \mathrm{v}_{\ell}\right)$ with $\mathrm{i} \neq \mathrm{q}$.
We have that $r\left(\mathbf{x} \mid \Omega^{\prime}\right)=r\left(c_{i} \mid \Omega\right)+(j-1)\left(\mathbf{1}_{\mathbf{t}}\right)$ and $r\left(\mathbf{y} \mid \Omega^{\prime}\right)=r\left(\mathrm{c}_{\mathrm{q}} \mid \Omega\right)+(\ell-1)\left(\mathbf{1}_{\mathbf{t}}\right)$. Assume that $\mathrm{r}\left(\mathbf{x} \mid \Omega^{\prime}\right)=\mathrm{r}\left(\mathbf{y} \mid \Omega^{\prime}\right)$. We know that, every nonzero coordinate of $\mathrm{r}\left(\mathrm{c}_{\mathrm{i}} \mid \Omega\right)$ is either 1 or 2 . If there exist a natural number $u$ such that the $u$-th coordinate of $r\left(c_{i} \mid \Omega\right)$ is equal to the $u$ th coordinate of $\mathrm{r}\left(\mathrm{c}_{\mathrm{q}} \mid \Omega\right)$, then $\mathrm{j}=\ell$. It follows that, $\mathrm{r}\left(\mathrm{c}_{\mathrm{i}} \mid \Omega\right)=\mathrm{r}\left(\mathrm{c}_{\mathrm{q}} \mid \Omega\right)$, a contradiction. Next, by Lemma 2, we may assume that there exist natural numbers $u$ and $v$ such that $d\left(c_{i}, S_{u}\right)=$ $1, \mathrm{~d}\left(\mathrm{c}_{\mathrm{i}}, \mathrm{S}_{\mathrm{v}}\right)=2$ and $\mathrm{d}\left(\mathrm{c}_{\mathrm{q}}, \mathrm{S}_{\mathrm{u}}\right)=2, \mathrm{~d}\left(\mathrm{c}_{\mathrm{q}}, \mathrm{S}_{\mathrm{v}}\right)=1$. From the u -th coordinate, $\ell+1=\mathrm{j}$ and from the $v$-th coordinate we have that,
$\ell=\mathrm{j}+1$
Therefore, j is equal to $\mathrm{j}+2$, a contradiction.
Theorem 2. Let $\Pi$ be a minimal resolving of $W_{n}$. If $W_{n} \triangleright_{o} P_{m}$ is a comb product graph where $o$ is a vertex of $\mathrm{P}_{\mathrm{m}}$ with degree 1 , then $\mathrm{pd}\left(\mathrm{W}_{\mathrm{n}} \triangleright_{\mathrm{o}} \mathrm{P}_{\mathrm{m}}\right) \leq \operatorname{pd}\left(\mathrm{W}_{\mathrm{n}}\right)+1$.

Proof. By Lemma 4, the comb product graph $W_{n} \triangleright_{0} P_{m}$ satisfy the inequality $\operatorname{pd}\left(W_{\mathrm{n}} \triangleright_{\mathrm{o}} \mathrm{P}_{\mathrm{m}}\right) \leq \mathrm{pd}\left(\mathrm{W}_{\mathrm{n}}\right)<\operatorname{pd}\left(\mathrm{W}_{\mathrm{n}}\right)+1$. Next, we assume that there exist $\mathrm{v} \in \mathrm{V}\left(\mathrm{W}_{\mathrm{n}}\right)$ such
that $\mathrm{r}(\mathrm{v} \mid \Omega)=2\left(\mathbf{1}_{\ell}\right)$ for some $\ell$. It is clear that $\mathrm{v} \neq \mathrm{c}$ where c is the center of the graph $\mathrm{W}_{\mathrm{n}}$. Let $\Omega=\left\{\mathrm{S}_{1}, \mathrm{~S}_{2}, \ldots, \mathrm{~S}_{\mathrm{k}}\right\}$. Assume, without loss of generality, that $\mathrm{c} \in \mathrm{S}_{1}$. We define the subsets of $\mathrm{V}\left(\mathrm{W}_{\mathrm{n}} \triangleright_{\mathrm{o}} \mathrm{P}_{\mathrm{m}}\right) \quad$ listed below: $\mathrm{S}_{1}^{\prime}=\left\{\left(\mathrm{c}, \mathrm{v}_{1}\right\} \cup\left\{\left(\mathrm{v}, \mathrm{v}_{\mathrm{j}}\right) \mid \mathrm{v} \in \mathrm{S}_{1}, \mathrm{v} \neq \mathrm{c}, \mathrm{j} \in[1, \mathrm{~m}]\right\}, \quad \mathrm{S}_{\mathrm{i}}^{\prime}=\right.$ $\left\{\left(\mathrm{v}, \mathrm{v}_{\mathrm{j}}\right) \mid \mathrm{v} \in \mathrm{S}_{\mathrm{i}}, \mathrm{j} \in[1, \mathrm{~m}]\right\}$ for every $\mathrm{i} \geq 2$, and $\mathrm{S}_{\mathrm{k}+1}^{\prime}=\left\{\left(\mathrm{c}, \mathrm{v}_{\mathrm{j}}\right) \mid 2 \leq \mathrm{j} \leq \mathrm{m}\right\}$. It follows that $\Omega^{\prime}=\left\{S_{1}^{\prime}, S_{2}^{\prime}, \ldots, S_{k}^{\prime}, S_{k+1}^{\prime}\right\}$ is a partition of $V\left(W_{n} \triangleright_{\mathrm{o}} \mathrm{P}_{\mathrm{m}}\right)$. The next step is to show $\Omega^{\prime}$ is a resolving partition.

It is obvious to verify that $\mathrm{r}\left[\left(\mathrm{c}, \mathrm{v}_{1}\right) \mid \Omega^{\prime}\right]=(\mathrm{r}(\mathrm{c} \mid \Omega), 1)=\left(\mathbf{1}_{1}, 1\right)=(0,1,1, \ldots, 1) \in \mathbb{Z}^{\mathrm{k}+1}$ and $r\left[\left(\mathrm{v}, \mathrm{v}_{1}\right) \mid \Omega^{\prime}\right]=\left(2_{\ell}, 2\right)=(2, . .2,0,2, \ldots, 2) \in \mathbb{Z}^{\mathrm{k}+1}$. If $\mathbf{x} \in \mathrm{S}_{\mathrm{k}+1}^{\prime}$, then $\mathrm{r}\left[\left(\mathrm{c}, \mathrm{v}_{\mathrm{j}}\right) \mid \Omega^{\prime}\right]=(\mathrm{j}-$ $1, j, j, \ldots, j, 0) \in \mathbb{Z}^{k+1}$. We conclude that $r\left[\left(c, v_{1}\right) \mid \Omega^{\prime}\right] \neq r\left[\left(v, v_{1}\right) \mid \Omega^{\prime}\right]$. Since $d\left(\left(c_{i}, v_{j}\right), S_{k+1}^{\prime}\right)=$ $j+1 \geq 2$, we also have that $r\left[\left(c, v_{1}\right) \mid \Omega^{\prime}\right] \neq r\left[\left(c_{i}, v_{j}\right) \mid \Omega^{\prime}\right]$. Note that $r\left[\left(v_{1}, v_{1}\right) \mid \Omega^{\prime}\right]=$ $(\mathrm{r}(\mathrm{v} \mid \Omega), 2)$ and $\mathrm{r}\left[\left(\mathrm{c}_{\mathrm{i}}, \mathrm{v}_{1}\right) \mid \Omega^{\prime}\right]=\left(\mathrm{r}\left(\mathrm{c}_{\mathrm{i}} \mid \Omega\right), 2\right)$. Since $\Omega$ is a resolving partition, $\mathrm{r}\left[\left(\mathrm{v}, \mathrm{v}_{1}\right) \mid \Omega^{\prime}\right] \neq$ $r\left[\left(c_{i}, v_{1}\right) \mid \Omega^{\prime}\right]$ for all i. For $j \geq 2$, we have that $d\left[\left(c_{i}, v_{j}\right), S_{k+1}^{\prime}\right]=j+1 \geq 3$. Therefore, $r\left[\left(v, v_{1}\right) \mid \Omega^{\prime}\right] \neq r\left[\left(c_{i}, v_{j}\right) \mid \Omega^{\prime}\right]$ for all $j \geq 2$. Let $\mathbf{x}$ and $\mathbf{y}$ be two vertices of $W_{n} \triangleright_{o} P_{m}$ with $\mathbf{x}, \mathbf{y} \in$ $S_{\mathrm{t}}^{\prime}$. It is obvious that $\mathrm{r}\left(\mathbf{x} \mid \Omega^{\prime}\right) \neq \mathrm{r}\left(\mathbf{y} \mid \Omega^{\prime}\right)$ if $\mathbf{x}, \mathbf{y} \in \mathrm{S}_{\mathrm{k}+1}^{\prime}$. For the last case, assume that $\mathbf{x}=$ $\left(c_{i}, v_{j}\right), y=\left(c_{q}, v_{\ell}\right) \in S_{t}^{\prime}$ with $q \neq i$ and $k+1 \neq t$. If $j \neq \ell$, then $d\left(\left(c_{i}, v_{j}\right), S_{k+1}^{\prime}\right) \neq$ $\mathrm{d}\left(\left(\mathrm{c}_{\mathrm{i}}, \mathrm{v}_{\ell}\right), \mathrm{S}_{\mathrm{k}+1}^{\prime}\right)$. Hence, $\mathrm{r}\left(\mathbf{x} \mid \Omega^{\prime}\right) \neq \mathrm{r}\left(\mathbf{y} \mid \Omega^{\prime}\right)$. If $\mathrm{j}=\ell$, then $\mathrm{r}\left(\mathbf{x} \mid \Omega^{\prime}\right)=\left(\mathrm{r}\left(\mathrm{c}_{\mathrm{i}} \mid \Omega\right)+(\mathrm{j}-\right.$ 1) $\left.\left(\mathbf{1}_{\mathbf{t}}\right), 1+\mathrm{j}\right)$ and $\mathrm{r}\left(\mathbf{y} \mid \Omega^{\prime}\right)=\left(\mathrm{r}\left(\mathrm{c}_{\mathrm{q}} \mid \Omega\right)+(\mathrm{j}-1)\left(\mathbf{1}_{\mathrm{t}}\right), 1+\mathrm{j}\right)$. If $\mathrm{r}\left(\mathbf{x} \mid \Omega^{\prime}\right)=\mathrm{r}\left(\mathbf{y} \mid \Omega^{\prime}\right)$, then $\mathrm{r}\left(\mathrm{c}_{\mathrm{i}} \mid \Omega\right)=\mathrm{r}\left(\mathrm{c}_{\mathrm{q}} \mid \Omega\right)$. This contradicts $\Omega$ as a resolving partition. We have proved that $\Omega^{\prime}=$ $\left\{\mathrm{S}_{1}^{\prime}, \mathrm{S}_{2}^{\prime}, \ldots, \mathrm{S}_{\mathrm{k}}^{\prime}, \mathrm{S}_{\mathrm{k}+1}^{\prime}\right\}$ is a resolving partition of $\mathrm{W}_{\mathrm{n}} \triangleright_{\mathrm{o}} \mathrm{P}_{\mathrm{m}}$. Consequently, $\mathrm{pd}\left(\mathrm{W}_{\mathrm{n}} \triangleright_{\mathrm{o}} \mathrm{P}_{\mathrm{m}}\right) \leq \mathrm{k}+$ $1=\mathrm{pd}\left(\mathrm{W}_{\mathrm{n}}\right)+1$.

We get the following result because of Theorem 1.
Corollary 2. For all integer $n \geq 4$ we have $p d\left(W_{n} \triangleright_{o} P_{m}\right) \leq p+2$, where $p$ is the lowest prime number that has the property of $p(p-1) \geq n$.

## 4. Conclusion

The $\operatorname{pd}\left(W_{n} \triangleright_{o} P_{m}\right)$ of the comb product is closely related to $\operatorname{pd}\left(W_{n}\right)$. The partition dimension of the comb product graph between the wheel and path graph has an upper bound, which we present by constructing its resolving partition from a resolving partition of $\mathrm{W}_{\mathrm{n}}$. We have proved that if $W_{n} \triangleright_{o} P_{m}$ is a comb product graph where o is a vertex of $P_{m}$ with degree 1 , then $\operatorname{pd}\left(W_{\mathrm{n}} \triangleright_{\mathrm{o}} \mathrm{P}_{\mathrm{m}}\right) \leq \operatorname{pd}\left(\mathrm{W}_{\mathrm{n}}\right)+1$.

## Acknowledgment

This research was supported by research grants Penelitian Internasional Binus (PIB) 2020. We owe a huge debt of gratitude to all of our collaborators for their help and support with this study.
